CIS 552: Database Design

**Homework – 1:**

## **Part 1: ER Schema – Conceptual Work**

Firstly, I have created the ER schema for Database MAIL\_ORDER in this one. By using some real-world applications, this schema contains gathering requirements from clients and creating an entity-relation plot to comprehend its business definition and what is happening behind the scenes of its execution.

In this section, we will learn how to design an ER schema based on text requirements. We may differentiate them by specification, an order processing system containing entities for customers, staff, and parts. We will have schema created for five tables like “EMPLOYEES”, “ORDERS”, “CUSTOMERS”, “PARTS”, and “PARTS QUANTITY” as soon as we design solicitation is released.

These tables will now include columns matching the qualities described in the requirements. With the knowledge that 0 to N employees can take orders and relationships are defined, but every order needs to have an associated employee. Similarly, 0 to N customers can have placed orders but all orders must need one associated customer. Therefore, an intermediate mapping table that has quantity of parts mapped with others.

# MAIL ORDER
